Abstract

Secondary metabolites which make the major contribution to specific odors and flavors of plants play a critical role when dealing as repellents against insects in storage pest management. Thus, identification of those secondary metabolites that have repulsive effect on insect pest behaviors could greatly facilitate the development of green pesticides while ensuring ecological sustainability. Hence, the present phytocentric research study provides the first investigation on volatile profile, chemical composition and repellent potential of the leaves of *R. graveolens* (Aruda) against the maize weevil, *Sitophilus zeamais* (Motschulsky) infestations. The volatile organic compound (VOC) profile of fresh leaves of *R. graveolens* was analyzed with headspace solid-phase microextraction coupled with gas chromatography and mass spectrometry (HS-SPME/GC-MS). Qualitative phytochemical screening of 11 phytoconstituents (alkaloids, saponins, flavonoids, tannins, steroids, terpenoids, anthraquinones, glycosides, phlobatannins, coumarins and phenols) for four leaf extracts (aqueous, n-hexane, ethyl acetate and methanol) was also performed following the standard procedures. In addition, contact and fumigant repellent properties of *R. graveolens* were also evaluated. A total of 14 compounds representing 99.95% of the total quantum of volatiles were detected in *R. graveolens* leaves consisting mainly of 2-ketones (93.32%), sesquiterpenoids (1.48%), aliphatic acids and esters (1.29%): 2-Nonanone (25.71%) and 2-Undecanone (55.51%) were the major volatile compounds followed by 2-Decanone (5.60%), 5, 6-diethyl-1-methyl-cyclohexene (3.76%), 2-Dodecanone (2.74%) and 2-Tridecanone (2.98%). Phytochemical results revealed the absence of phlobatannins and the presence of alkaloids, glycosides and coumarins in each leaf extract. Aqueous leaf extract exhibited the presence for majority of phytoconstituents while hexane demonstrating the least presence. The data on contact and fumigation repellency against *S. zeamais* indicated strong maize grain protection activities at the highest dosage accounting for 97% and 96% respectively. The present study provides the evidence that *R. graveolens* leaves contain agriculturally important bioactive secondary plant metabolites, thus justifying the use of plant species with respect to its significant repellent role against *S. zeamais* populations in post-harvest storage pest management programs.
